Section 1 Aquatic Macroinvertebrates

1.0 Introduction

Aquatic macroinvertebrates are insects and other invertebrates living in streams, rivers, lakes, and estuaries. Aquatic macroinvertebrate communities can be useful indicators of water quality because they respond to integrated stresses over time, and reflect fluctuating environmental conditions. Community response to various pollutants (e.g. organic, toxic, and sediment) may be assessed through interpretation of diversity, known organism tolerances, and in some cases, relative abundance and feeding behavior types.

Regional ambient monitoring generates data, which represent the general biological condition of state waters that may be subject to a variety of point and nonpoint source impacts. The Aquatic Biology Section (ABS) uses these ambient macroinvertebrate data to support a variety of state and federal programs. Additionally, special macroinvertebrate studies are conducted at various sites to evaluate specific potential point and nonpoint source pollution impacts.

1.1 Field Collection Methods

1.1.2 Timed-qualitative Multiple Habitat Sampling Protocol

The ABS uses a timed-qualitative, multiple habitat sampling protocol (MHSP) to collect macroinvertebrates. Multiple habitat sampling of some type is widely used by many regulatory and non-regulatory agencies both in the United States and abroad (Barbour, et al., 1997; USEPA, 1997; Marchant, et al., 1997). The greatest benefit from using the MHSP is that it enables resource managers to collect representative macroinvertebrate taxa from the wide variety of natural habitats in a stream. Since macroinvertebrates occupy a variety of habitat types, many taxa may be excluded when only select habitats are sampled by specific sampling devices (e.g. Surber net, Ponar dredge, etc.). This may lead to exclusion of a variety of taxa and spurious assessments.

At ambient monitoring sites, a team of two or three biologists (never less than two) samples for aquatic macroinvertebrates for approximately three person-hours (three person-hours represent three biologists sampling for one hour, or two biologists sampling for one and one half hours). With the aid of a D-frame dip net, kick net, metal sieve, white pan, bucket and a fine mesh sampler, all the available natural habitats are sampled. Macroinvertebrates are also collected directly from the habitat with forceps. All macroinvertebrates are placed in jars or vials filled with 85% ethanol (EtOH) and labeled with the station number and collection date. If a station number has not been established, other data such as county, stream name, and nearest road is listed on the label. It is highly desirable to list the latitude and longitude on the label unless this information is readily available through a geographic information system.

The goal of the sampling team is to collect as many different macroinvertebrate taxa as possible during the allotted time. Although the MHSP is a qualitative method, the actual collection of

samples is a disciplined procedure designed to ensure that all the habitats present at a site are thoroughly sampled, irrespective of what types of habitat are available or where the sample is collected. Rivers and streams from the mountains to the coastal plain of South Carolina vary in habitat type and amount available for colonization by macroinvertebrates. For example, mountain sites are often dominated by rock/gravel riffle stream substrate, woody debris, and root wads, while coastal sites may be dominated by aquatic vegetation, woody debris, and sandy to muddy stream substrate. Between the mountains and coastal plain lies the piedmont, which has a combination of some or all of the above habitats. Regardless of what region or what kind of habitat is being sampled, the MHSP insures that an adequate representation of the macroinvertebrate community is obtained. The following is a discussion of the MHSP with detailed steps on how to properly collect macroinvertebrate samples from the variety of stream habitats.

A. Chironomidae and Small Macroinvertebrate Collection Procedure

A very important component of the macroinvertebrate community is the midge family Chironomidae. Midge larvae often account for at least 50% of the total species diversity in most aquatic systems (Merritt et al., 2008). Since midges are relatively small, they are collected with fine mesh samplers. The fine mesh samplers are made with Nytex (micro-screen cloth material) that has a mesh size of 300 μm . One sampler is a mesh bag, 0.5 m by 1.0 m, made from a folded sheet of Nytex sewn together on two sides. This bag is used to collect midges from the sand. The other sampler is a 13 cm long by 10 cm diameter piece of PVC pipe with a Nytex covering on one end. This is used to strain water from the bucket into which midges are washed from the habitats. Although the objective of the fine mesh net is to collect midges, it can also collect other small macroinvertebrates.

Collection Steps:

1. Fill a 19 liter bucket approximately one half full with water.
2. Collect two or three samples of all the habitat types present at a stream site by hand (rocks, sticks, leaf packs, root wads, etc.) and rinse in the bucket to remove midges and other macroinvertebrates. Attached root wads and vegetation may be rinsed directly in the bucket without detachment.
3. Since some midge taxa are sand dwellers, select a sandy bottom site in the stream and collect midges by placing the small mesh bag on the bottom with the open end facing upstream. Disturb approximately a 1 m^2 area of the sand upstream of the bag and let the sand and midges drift into the bag. In areas with little current, the sandy area can be disturbed and the bag swept back and forth over that area to capture the midge larvae. Collect three sand samples from three different areas of the stream. The bag is only used when there are sandy bottom areas available.
4. Empty the contents of the bag into the same bucket of water that contains the other habitat washes and rinse the bag up and down in the bucket to remove the attached midges.

5. Rinse and remove by hand as much of the larger debris as possible from the bucket and discard. Stir the water in the bucket and strain through the Nytex covered pipe.
6. Remove small portions of the detritus left in the bottom of the Nytex pipe and place in a white pan 1/4 filled with water. Spread the detritus evenly in the pan by hand so that the macroinvertebrates can be seen against the white background. With the aid of forceps and an eye-dropper, collect the midges and other small macroinvertebrates and preserve them in a jar filled with 85% EtOH.
7. Repeat step 6 until all the detritus in the Nytex pipe has been examined.

Do not collect more than 100 midges, but collect them in relative proportion to the size classes present. Other macroinvertebrates are sampled proportional to the relative abundance in each pan picked. Although the emphasis of the fine mesh sampler is to collect small macroinvertebrates, larger macroinvertebrates are also collected as they are encountered.

B. D-frame Dip Net Collection Procedure

The habitat type most often sampled with the dip net is root wad habitat. Root wads are present at most stream sites, often at the margins, and they support a variety of small caddisflies and other taxa. Aquatic vegetation, when present, is also sampled with the dip net.

Collection Steps:

1. Root wads are sampled by repeatedly jabbing a D-frame dip net (500 µm mesh size) upwardly into the roots along a stretch of bank until the net is about 1/4 full of detritus and root debris. Several root wads are washed down by hand into the dip net to remove firmly attached macroinvertebrates. Aquatic vegetation is sampled by sweeping the dip net through the vegetation two or three times.
2. Rinse the bottom of the dip net in the stream to remove excess mud and silt. If excess sediment or silt is present it is helpful to rinse the sample by dipping water into the net and allowing it to drain while swirling the contents with your hand. This can be done several times in rapid succession. Remove small portions of the detritus left in the net and spread it evenly in a white pan 1/4 filled with water. Do not attempt to sort through so much detritus that the bottom of the pan is obscured.
3. Using forceps, remove macroinvertebrates from the pan and place in a jar of 85% EtOH. It is helpful to allow the contents of the pan to settle and become still. This facilitates seeing the small macroinvertebrates as they begin to move about.

Based on the quality of the root banks and/or aquatic vegetation, collect one or two dip net samples in the root banks and two or three samples in the aquatic vegetation.

C. Kick Net Collection Procedure

The kick net is a 1.0 m² sheet of Nytex (500 -1000 µm mesh size) attached on two sides to 1.5 m long poles. The kick net is used to sample rock/gravel riffles and snags/leaf packs.

Collection Steps:

1. Place the kick net slightly downstream of the area to be sampled (snags/leaf packs and/or rock/gravel riffle). Disturb about 1 m² of the habitat and catch the debris and macroinvertebrates that drift into the net.
2. Spread the kick net out on a sand bar or a flat area on the bank and collect macroinvertebrates from the net with forceps and preserve them in a jar of 85% EtOH. Alternatively, the net can be rinsed into a large white pan and the macroinvertebrates picked from there.

If the habitat is mostly snags/leaf packs, a minimum of two kick net samples should be taken there. If the habitat is a mix of both rock/gravel riffle and snags/leaf packs, a minimum of one kick net sample should be taken from each habitat. In streams that are mostly rock/gravel riffle, a minimum of two kick net samples should be taken in the riffle areas. One kick net sample should be taken from a high velocity riffle area and the other from a low velocity riffle area.

D. Sieve Collection Procedure

Sieves are used to sample sand and sediment as well as other habitat types during visual collections. Sieve sizes used are the U.S. #30 (0.6 mm openings) and the U.S. #10 (2.0 mm openings). The #10 sieve is used primarily to sample sand and sediment. The #30 can be used as an aid to sweep and to hold material from all habitat types. The sieve enables the biologist to sample large amounts of habitat quickly and is invaluable for collecting sediment-dwelling taxa such as: Odonata (dragonflies), Gastropoda (snails), Pelecypoda (clams, mussels), sand case building and burrowing caddisflies (Molannidae, Sericostomadidae, Dipseudopsidae, Odontoceridae), and Ephemeridae (burrowing mayflies).

Collection Steps:

1. Visually inspect the sand and mud for signs of macroinvertebrate activity. For example, the movement of burrowing odonates and mussels leaves trails in the sand. Small holes can be seen in the mud, clay, or sand in areas where burrowing mayflies are found. The tubes of *Phylocentropus* sp. larvae can often be seen extending above the substrate where they are present.
2. With the #10 sieve, sample the mud or sand where there are signs of macroinvertebrate

activity. Sift the sand, mud, silt, and detritus in the stream to trap macroinvertebrates in the sieve.

3. Collect macroinvertebrates from the sieve and place them in jar of 85% EtOH.

4. The #30 sieve can be used to sample root wad and snag sites. Process as above.

E. Visual Collection Procedure

Collections using the kick net, d-frame net and the fine mesh samplers generally require a total of 1.5 person-hours to complete. For an additional 1.5 person-hours, stream habitats are visually searched for macroinvertebrates, and collected directly from the habitat with forceps and placed in jars filled with 85% EtOH. This requires sieving sediment and removing rocks and logs from the water for inspection. For example, rocks and logs are searched for taxa such as the retreat building *Psychomyia* sp. (caddisfly) and for retreat building Hydropsychidae. The undersides of rocks are examined for macroinvertebrates such as Ephemeroptera (mayflies), Plecoptera (stoneflies), Gastropoda (snails), Psephenidae (water pennies) and Megaloptera (hellgrammites). The crevices in rocks and logs are searched for caddisflies such as *Nyctiophylax* sp., *Pycnopsyche* sp., and *Ceraclea* sp. Decaying logs are picked apart to reveal midges and other taxa. Aquatic vegetation, sticks, and limbs are visually searched for small caddisflies (Hydroptilidae and Brachycentridae) and other macroinvertebrates. Mature leaf packs, snags, and root wads are sampled to collect a variety of other macroinvertebrates. Unionid mussels are located using the #10 sieve as well as by sight and by feeling in the sediment. These are identified in the field, photographed, and released unharmed into the same habitat type from which they were collected.

F. Collection Procedures Summary

No attempt is made to collect all specimens encountered. If a taxon can be reliably identified in the field, only 10-15 specimens are collected, other taxa are collected in approximate proportion to their abundance in each sampling method (net, pan, sieve, etc.). Since the emphasis of the MHSP method is to collect different taxa, abundance is considered only in a relative sense (see Data Analysis). Some taxa are not collected including: Nematoda, Collembola, semiaquatic Coleoptera, and all Hemiptera except Naucoridae, Belostomatidae, Corixidae, and Nepidae. These are not collected because they are most often found on the water surface or on the banks, and are generally thought of as semiaquatic.

There is no established distance of stream reach sampled at any particular site. If there is good, fairly evenly distributed natural habitat, approximately 100 m of stream (both sides) is routinely sampled. In streams where there is sparse habitat, the distance covered may be more than 100 m. For ambient monitoring activities most sites are accessed at road bridges and are sampled upstream of the bridge, however, some situations may warrant sampling downstream (e.g. access and/or habitat limitations).

As previously noted, the MHSP is a three person-hour sampling effort. Approximately one half hour is devoted to use of the kick net, one half hour is devoted to use of the d-frame dip net, and about one half hour is devoted to the fine mesh samplers. The rest of the time (one and one half person hours) is spent using sieves and forceps to make visual collections of all habitat types present.

As a general rule, when teams of biologists sample a site, each one independently uses one of the three sampling devices (dip net, kick net, fine mesh nets) to sample the appropriate habitat. Upon completion, visual collections are begun and the sieve is used extensively. It is helpful for the sampling team to discuss the kinds and numbers of taxa present and absent at a site. This results in more efficient sampling. It is important that the field staff be trained and experienced macroinvertebrate taxonomists to use the MHSP effectively.

High water conditions can impair sampling efficiency by making some critical habitats inaccessible due to water depth and clarity. An underestimate of taxa richness may lead to spurious results. If high water levels and turbid conditions make sampling difficult, it is better to return to the site under more amenable sampling conditions.

When sampling large rivers, a boat or kayaks may be used to access the habitats for sampling. The sampling methodology remains the same but the duration may be increased to insure that all natural habitats have been adequately sampled. In shallow areas, the river is sampled as a wadeable stream. Otherwise, the available habitat is sampled from the boat with dip nets and sieves and/or by dragging logs, sticks, root wads, etc., into the boat. A clam rake can help to reach and bring up habitat in deep areas as well as to find Unionid mussels. A ponar may be used to reach sediment-dwelling organisms in deep areas.

Photographs are taken of the upstream and downstream ends of the reach sampled at each station in order to document conditions on the sampling day. It is a good idea to also take photos when a site is visited but not sampled. Photos are kept in an electronic file and named in the format STN-designation-mo.day.yr (for example E-042-dn-8.10.17) so that they can be easily retrieved. Any mussel photos are included in this file as well. Ensure that photo files are labeled correctly by using the camera's date/time stamp and downloading them soon after returning to the lab.

1.1.3 Equipment

1. D-frame dip net
2. Kick net
3. U.S. # 10 Sieve
4. 13 cm (length) by 10 cm (dia) PVC fine mesh sampler
5. Fine mesh bag
6. 19 liter bucket
7. White pans
8. Forceps
9. Collection vials and jars filled with 85% EtOH

10. Collection labels and EtOH-proof pen or pencil
11. Physicochemical parameter equipment (multi-parameter meter or equivalent)
12. Camera

Optional

13. U.S. # 30 Sieve
14. Ponar
15. Clam rake

1.2 Habitat Assessment

Habitat assessment is an important step towards understanding the effects of pollution on macroinvertebrate communities. The ABS conducts two kinds of habitat assessment at each sampling site. The first is a comprehensive assessment adopted from the Environmental Protection Agency's (EPA) *Revisions to Rapid Bioassessment Protocols for Use in Streams and Rivers* (Appendix 1), and the second is a simplified form developed to meet specific needs of the ABS (Appendix 2). Instructions are included on the forms explaining how to evaluate each of the habitat metrics. Habitat metrics are independently evaluated by each biologist and averaged for a final score (on a single form).

The EPA habitat assessment (EPA-HA) provides a thorough evaluation of several conditions at a stream site that could affect stream habitat quality. It provides clues to why certain habitat types may be present or absent, and information about the general stream condition at the assessment site. Since the EPA-HA is a standardized form, it is very useful for reporting purposes and sharing data among the Southeastern states. In South Carolina the EPA-HA high gradient form is used in Blueridge and Piedmont ecoregions while the low gradient form is used for the Southeastern Plains and the Middle Atlantic Coastal Plains.

The simplified habitat assessment form (ABS-HA) provides more detailed information about instream macroinvertebrate habitat. It enables ABS biologists to make better assessments on the role of stream habitat in situations where pollution is involved. The form classifies the habitat into five categories and rates them from excellent to non-existent. This permits visualization of the habitats when the data are being analyzed, and helps to explain the presence or absence of certain taxa. In addition, the ABS-HA helps ABS biologists to cluster stations according to shared habitats when comparisons are made among stations.

1.3 Physicochemical Sampling Procedures

The stream dissolved oxygen, pH, temperature, and conductivity are measured at the time of macroinvertebrate sampling. Results are recorded in the Field Quality Control Logbook (Appendix 3). Specific operation and calibration procedures are followed as documented in the most recent version Environmental Investigations Standard Operating Procedures and Quality Assurance Manual (SCDHEC).

1.4 Laboratory Methods

1.4.1 Sample Handling and Identification

At the end of each sampling day EtOH is decanted and the samples are reconstituted with fresh 85% EtOH. After returning to the ABS laboratory the samples are logged into the Macroinvertebrate Central Receiving Logbook (MCRL) (Appendix 4) and stored in a locked cabinet to await further processing.

Before the sorting and identification of a macroinvertebrate sample begins, the taxonomist assumes custody of the sample by signing for it in the MCRL. Custody remains with the taxonomist until the sample has been identified and these data are recorded. Sample completion is noted in the MCRL.

Macroinvertebrates are generally sorted by taxonomic order and placed into separate vials or petri dishes for further identification. Specimens not requiring slide mounting are identified using a stereo dissecting scope capable of at least 50x magnification. Midges, some baetid mayflies, and on occasion other taxonomic groups are mounted on labeled (date and locality) slides with CMC-10 mounting media and identified with a compound microscope capable of 1000x magnification. Identifications are made to the lowest practical taxonomic level using the appropriate taxonomic references. When reliable keys are available and specimens are mature, this is typically species level for the EPT taxa and genus level for other groups though there are some exceptions. The NC Department of Environmental Quality has provided online taxonomic guides which include suggested levels of taxonomic effort for the orders Ephemeroptera, Plecoptera, Trichoptera, and Coleoptera (Beaty, S. R. 2010, 2011, 2013, 2015). Staff in the DHEC Aquatic Biology Section have found these to be useful and appropriate for most South Carolina species.

Midges are transferred to water and allowed to settle before mounting. A drop of CMC-10 mounting media is placed on a labeled slide, and the specimen(s) is oriented in the media so that the ventral side of the head capsule is up. To get the head arranged properly, it may be necessary to separate it from the body. A cover slip is placed over the specimen and gentle pressure is applied to spread the mouthparts. Several midges may be mounted on one slide. Slides are allowed to dry at least two days before identification.

Baetidae and certain other taxa that require slide mounting are set aside in a petri dish and the entire body or body parts are mounted, as necessary, for identification. A drop of CMC 10 mounting media is placed on a labeled slide. The whole specimen or parts such as the head or legs are placed in the drop of CMC 10 and with forceps, a cover slip is placed over the specimen. Gentle pressure is applied to the cover slip to reveal the structures necessary for identification. Several specimens may be mounted on one slide. Slides are allowed to dry at least two days before identification.

After the sorted macroinvertebrates (except Chironomidae and some Baetidae) from a station

have been identified and these data recorded on bench sheets, they are placed together in a single jar of 85% EtOH. This jar is labeled with station, date collected, and person who identified the sample, and is stored at least five years in the ABS voucher collection. If a new taxa record (i.e. one not previously collected from South Carolina) is identified from a site, it is removed from the voucher collection and stored separately in the ABS reference collection. A note is made on a bench sheet (a form used to record the number of taxa and specimens identified) when a specimen is relocated to the reference collection. Slide mounted specimens are stored separately in cabinets according to sample date and station. If mounted Chironomidae or other taxa are transferred to the reference collection, this is noted on the bench sheet.

1.4.2 Data Analysis

The taxa list, physicochemical data, and habitat information are entered into a computer data base. This program is used for data management and reporting purposes.

Because the MHSP is a timed-qualitative method, metrics that require quantitative collection methods are not used. Two metrics that have proven to be very effective in evaluating macroinvertebrate data collected by qualitative methods are the EPT and biotic indices (Lenat, 1993; Wallace, 1996; Barbour, 1997). The EPT index is the total number of distinct Ephemeroptera (mayflies), Plecoptera (stoneflies), and Trichoptera (caddisflies) taxa collected at a site. Most EPT taxa are very intolerant of pollution and, in general, a high EPT count indicates excellent water quality.

The biotic index (BI) is the average pollution tolerance of all organisms collected (based on assigned index values for taxa) and the calculation factors in relative abundances. The index is based on a scale from 0 to 10, with 10 representing the most impaired stream conditions.

$$\text{Biotic Index (BI)} = \sum(TVi)(ni)/N$$

TV_i = *i*th taxon tolerance value
n_i = *i*th taxon abundance value
N = sum of all abundance values

This index and the associated tolerance values were developed in North Carolina (Lenat, 1993) and the SCDHEC uses a modification of these values (Appendix 5). Taxa with no assigned tolerance value are excluded from the biotic index calculation.

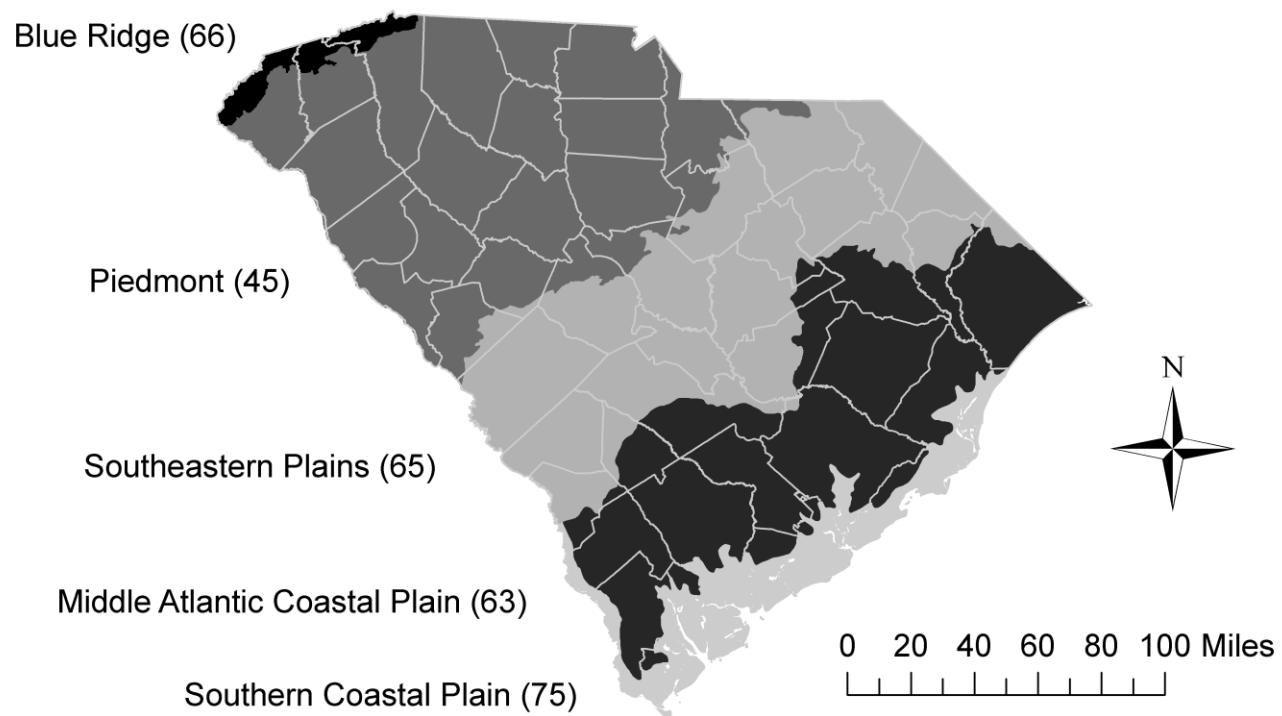

The calculation of the BI does not include all specimens collected in a sample but rather a maximum of 10 specimens per taxon. This is done to ensure that the BI for a site will not be biased because some taxa are more successfully collected than others. Since most taxa cannot be accurately identified in the field, it is common for some taxa to be more abundant in a sample. Taxa collected from freshwater streams are designated as Rare (1-2 individuals), Common (3-9 individuals) or Abundant (≥ 10 individuals) and are assigned a 1, 3, and 10, respectively, for the calculation of the BI. If there are less than 100 total organisms in a sample, the BI is not used.

Instead, the EPT index is used along with other data to assign a bioclassification.

Macroinvertebrate communities change across ecoregions so different BI and EPT criteria are used to establish bioclassifications for streams based on the ecoregion in which they occur.

Figure 1 shows the ecoregions in South Carolina (after Omernik 1987, and Griffith et. al 2002). Macroinvertebrate Biocriteria have been established for 3 of South Carolina's 5 level III ecoregions: Blue Ridge (66), Piedmont (45), and Southeastern Plains (65). Numeric biocriteria for the Middle Atlantic Coastal Plain (63) have yet to be fully developed but are currently being evaluated. Many of the streams in this ecoregion are swamp-like and become dry or stagnant in the summer months. Thus the macroinvertebrate diversity in these systems is often low and the organisms that are present tend to be hardy species that can tolerate extreme environmental conditions. This makes the stressor signal weak and often it is difficult to distinguish anthropogenic perturbation from natural environmental conditions.

Figure 1. Level 3 Ecoregions of South Carolina
(after Omernik, 1987)

Bioclassification of streams in South Carolina is based on the combination of equally weighted BI and EPT scores, and parallels North Carolina's criteria range:

Excellent = 5 Good = 4 Good-Fair = 3 Fair = 2 Poor = 1

Since North Carolina and South Carolina share similar ecoregions, the North Carolina bioclassification criteria are applied to South Carolina streams. The following linear equations are used to determine the scores for the EPT taxa richness values and BI values. These produce scores as a continuous variable roughly equivalent to those found in Lenat, 1993. The highest and lowest values remain 5.0 and 1.0 respectively.

EPT Scores

SE Plains	Score = 0.1431 x EPT index + 0.568
Piedmont and Blue Ridge	Score = 0.1247 x EPT index + 0.568

Biotic Index Scores

SE Plains	Score = -1.3599 x biotic index + 11.832
Piedmont and Blue Ridge	Score = -1.3241 x biotic index + 11.264

The biotic index score and the EPT score are averaged together to produce a combined score, which determines the final bioclassification. Rounding is used only to format the combined score to show a single decimal place and this is done using the standard rules where digits of five or greater round up while digits under 5 round down.

Bioclassification of streams is important because it helps resource manager's prioritize cleanup and protection efforts. This information is reported in the 305b report to the United States Environmental Protection Agency. The Clean Water Act (Section 305b) requires that States report the conditions of their waters to congress. In the 305b report, macroinvertebrates are used to make a determination on a stream's level of aquatic life use support (ALUS). The criteria used to measure ALUS are summarized in three categories: Fully Supporting, Partially Supporting and Not Supporting.

Fully Supporting: Reliable data indicate functioning, sustainable biological assemblages (e.g. fish, macroinvertebrates, or algae) none of which has been modified significantly beyond the natural range of the reference condition.

Partially Supporting: At least one assemblage indicates moderate modification of the biological community as compared to the reference condition.

Not Supporting: At least one assemblage indicates a severely impacted macroinvertebrate community. Data clearly indicate severe modification of the biological community compared to the reference condition.

The Aquatic Biology Section determines the ALUS based on the bioclassification of the stream:

<u>Combined Score</u>	<u>Bioclassification</u>	<u>ALUS</u>
4.5 – 5.0	Excellent	Fully Supporting
3.5 -4.4	Good	Fully Supporting
2.5 - 3.4	Good-Fair	Partially Supporting
1.5 – 2.4	Fair	Partially Supporting
1.0 – 1.5	Poor	Not Supporting

This method is also used to make stream impairment judgments for South Carolina's Watershed Water Quality Management Strategy and for point/nonpoint source impact assessments.

1.4.3 Data Analysis for Special Studies

Special studies often involve using sites upstream from a point source discharge or a non-point source area as a control. The site downstream from the potential impact can then be compared with this upstream reference station for assessment purposes. By comparing final bioclassification scores an assessment can be made. The following represents the levels of impairment and their associated change in bioclassification scores.

Level of Impairment Decrease in Bioclassification Score

Unimpaired	<0.5
Slightly Impaired	0.6-1.5
Moderately Impaired	1.6-2.5
Severely Impaired	>2.5

The above scale is used as a general guide and there are situations in both special studies and routine monitoring where professional judgment of the Aquatic Biology Section may override the assessment metrics. This is common practice in areas such as the Mid-Atlantic Coastal Plain where criteria are still being developed. Another example is when the control is also impaired. This is common in urban watersheds where the biological community is often stressed (see Allen 2004 for a review). In such streams if the control is Poor (1.0), for example, it is a mathematical impossibility to show a decrease in the bioassessment score since 1.0 is the lowest category. This is not to suggest that the point source discharge could not contribute to degradation of water quality. In this situation, water chemistry, toxicity tests, or other means may be more appropriately used to determine the potential for an effluent to cause degradation. However even

in these situations biassessments can be valuable. The change in species composition, feeding groups, or habits of the animals making up the macroinvertebrate communities can sometimes help determine impact. These studies can also help track long-term trends or provide clues to catastrophic events in which substantial numbers of species are missing from a downstream site relative to the control.

In situations where a bioclassification cannot be calculated for a downstream site due to a paucity of organisms, an assessment of impact will be based on weight of evidence. Metrics such as EPT taxa richness, total taxa richness, and abundance of organisms will be used to compare the control site with the study site.

1.5 Quality Assurance

All macroinvertebrate samples are logged into the Aquatic Biology Section's Macroinvertebrate Central Receiving Logbook upon delivery to the lab. Entries on the Macroinvertebrate Sampling Form are checked for agreement as to the number of jars and vials of samples collected from each station. The logbook serves to track sample possession and to document progress through initial log in, sorting, taxonomic identification, and data recording. The number of jars and/or vials containing the samples at each phase of sample processing, identification, and storage is recorded in the logbook. The identification data are recorded on a macroinvertebrate bench sheet. Completed bench sheets along with habitat assessment forms and any other hard copy related to a sample are kept on permanent file. Using the completed bench sheet, the data are then entered into a computer database. After data are entered into the database they are printed out on spreadsheets. These spreadsheets are compared to the original bench sheets and corrections made if needed.

Ten percent of all identified samples are selected at random to be evaluated for taxonomic accuracy. The quality assurance (QA)/quality control (QC) reviewer records the findings in the permanently bound Macroinvertebrate QA/QC Logbook (Appendix 7). Count accuracy is also checked and similar QA/QC measures (checking counts of other samples identified by errant taxonomist) are taken if average count error (all taxa) exceeds 10%. A sample is chosen for QA/QC after 10 samples have been identified. Each set of 10 completed samples is numbered. A single sample is randomly chosen by picking a coin from a jar of coins numbered one through ten. Each taxonomist is assigned a number and is chosen to perform QA/QC by random picking from numbered coins. The taxonomist that conducted the initial identifications is not eligible to conduct QA/QC on that sample. Disagreements are resolved between the QA/QC taxonomist and the original taxonomist, and the results are recorded in the QA/QC logbook.

To evaluate the precision of the field techniques 10% of the stations are sampled twice. This involves the selection of two adjacent stream reaches on the same stream. Each reach should be similar to each other with respect to habitat and hydrology. Each reach is sampled using the timed MHSP described above preferably on the same day. Each reach is treated as a separate station with a final bioclassification score calculated for each segment. Precision is determined by comparing the two bioclassification scores, which ideally should be the same.

Taxonomists use current, accepted taxonomic references in making identifications as well as in interpreting the results. The texts “*Larvae of the Southeastern USA Mayfly, Stonefly, and Caddisfly Species*” (Morse et al., 2017) and the fourth edition of “*An Introduction to the Aquatic Insects of North America*” (Merritt et al., 2008) have been found to be particularly useful. In addition, primary literature is kept on file and used when the above keys are not appropriate. Taxonomists also attend workshops and training sessions when available to expand their knowledge and competence and to remain current in the ever-changing realm of taxonomy.

1.6 Index Period

For ambient monitoring SCDHEC’s index period is 15 June to 15 September for the Blueridge, Piedmont, and Southeastern Plains ecoregions while it is 15 January to 15 March in the Middle Atlantic Coastal Plain Ecoregion. Attempts are made to stay away from the margins of these date brackets if time permits. Special studies in which an upstream control site can be used theoretically can be conducted at any time of the year. A summer sample is often used but recent findings demonstrate that a winter sample may be more valuable, particularly in small watersheds. This is because the upstream control often has a better macroinvertebrate community when water levels are higher and more stable, making any potential change more noticeable.

Appendix 1. EPA Habitat Assessment Forms (high gradient for mountain and piedmont ecoregions)

HABITAT ASSESSMENT FIELD DATA SHEET

HIGH GRADIENT

Date _____ Collectors _____
 Station No. _____ Location _____

Habitat parameter	Condition category																				
	Excellent			Good			Fair			Poor											
1. Epifaunal (bottom) substrate / available cover	Greater than 70% of substrate favorable for epifaunal colonization and fish cover; mix of snags, submerged logs, undercut banks, cobble or other stable habitat and at stage to allow full colonisation potential (i.e. logs/snags that are not new fall and not transient).						40-70% mix of stable habitat; well-suited for full colonization potential; adequate habitat for maintenance of populations; presence of additional substrate in the form of newfall, but not yet prepared for colonization (may rate at high end of scale).						20-40% mix of stable habitat; habitat availability less than desirable; substrate frequently disturbed or removed.								
SCORE	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
2. Embed-dedness	Gravel, cobble and boulder particles are 0-25% surrounded by fine sediment. Layering of cobble provides diversity of niche space.						Gravel, cobble and boulder particles are 25-50% surrounded by fine sediment.						Gravel, cobble and boulder particles are 50-75% surrounded by fine sediment.						Gravel, cobble and boulder particles are more than 75% surrounded by fine sediment.		
SCORE	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
3. Velocity / depth regime	All four velocity/depth regimes present (slow-deep, slow-shallow, fast-deep, fast-shallow). Slow is <0.3m/s, deep is >0.5m).						Only 3 of the 4 regimes present (if fast-shallow is missing, score lower than if missing other regimes).						Only 2 of the 4 habitat regimes present (if fast-shallow or slow-shallow are missing, score low).						Dominated by 1 velocity/depth regime (usually slow-deep).		
SCORE	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
4. Sediment deposition	Little or no enlargement of islands or point bars and less than 5% of the bottom affected by sediment deposition.						Some new increase in bar formation, mostly from gravel, sand or fine sediment; 5-30% of the bottom affected; slight deposition in pools.						Moderate deposition of new gravel, sand or fine sediment on old and new bars; 30-50% of the bottom affected; sediment deposits at obstructions, constrictions and bends; moderate deposition in pools prevalent.						Heavy deposits of fine material, increased bar development; more than 50% of the bottom changing frequently; pools almost absent due to substantial sediment deposition.		
SCORE	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
5. Channel flow status	Water reaches base of both lower banks, and minimal amount of channel substrate is exposed.						Water fills >75% of the available channel; or <25% of channel substrate is exposed.						Water fills 25-75% of the available channel, and/or riffle substrates are mostly exposed.						Very little water in channel and mostly present as standing pools.		
SCORE	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Appendix 1. EPA Habitat Assessment Forms (high gradient for mountain and piedmont ecoregions)

Habitat parameter	Condition category																				
	Excellent			Good			Fair			Poor											
6. Channel alteration	Channelization or dredging absent or minimal; stream with normal pattern.			Some channelization present, usually in areas of bridge abutments; evidence of past channelization, i.e. dredging (greater than 20 yr) may be present, but recent channelization is not present.			Channelization may be extensive; embankments or shoring structures present on both banks; and 40 to 80% of stream reach channelized and disrupted.			Banks shored with gabion or cement; over 80% of the stream reach channelized and disrupted. Instream habitat greatly altered or removed entirely.											
SCORE	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
7. Frequency of riffles (or bends)	Occurrence of riffles relatively frequent; ratio of distance between riffles divided by width of the stream <7:1 (generally 5 to 7); variety of habitat is key. In streams where riffles are continuous, placement of boulders or other large, natural obstruction is important.			Occurrence of riffles infrequent; distance between riffles divided by the width of the stream is between 7 to 15.			Occasional riffle or bend; bottom contours provide some habitat; distance between riffles divided by the width of the stream is between 15 to 25.			Generally all flat water or shallow riffles; poor habitat; distance between riffles divided by the width of the stream is a ratio of >25.											
SCORE	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
8.Bank stability (score each bank)	Banks stable; evidence of erosion or bank failure absent or minimal; little potential for future problems. <5% of bank affected.			Moderately stable; infrequent, small areas of erosion mostly healed over. 5-30% of bank in reach has areas of erosion.			Moderately unstable; 30-60% of bank in reach has areas of erosion; high erosion potential during floods.			Unstable; many eroded areas; 'raw' areas frequent along straight sections and bends; obvious bank sloughing; 60-100% of bank has erosional scars.											
Left Bank	10	9	8	7	6	5	4	3	2	1	0										
Right Bank	10	9	8	7	6	5	4	3	2	1	0										
9.Vegetative protection (score each bank)	More than 90% of the streambank surfaces and immediate riparian zone covered by native vegetation, including trees, understory shrubs, or non woody macrophytes; vegetative disruption through grazing or mowing minimal or not evident; almost all plants allowed to grow naturally.			70-90% of the streambank surfaces covered by native vegetation, but one class of plants is not well-represented; disruption evident but not affecting full plant growth potential to any great extent; more than one half of the potential plant stubble height remaining.			50-70% of the streambank surfaces covered by vegetation; disruption obvious; patches of bare soil or closely cropped vegetation common; less than one-half of the potential plant stubble height remaining.			Less than 50% of the streambank surfaces covered by vegetation; disruption of streambank vegetation is very high; vegetation has been removed to 5 centimetres or less in average stubble height.											
Left Bank	10	9	8	7	6	5	4	3	2	1	0										
Right Bank	10	9	8	7	6	5	4	3	2	1	0										
10.Riparian zone (score each bank)	Width of riparian zone >18 metres; human activities (i.e. roads, lawns, crops etc.) have not impacted the riparian zone.			Width of riparian zone 12-18 metres; human activities have impacted riparian zone only minimally.			Width of riparian zone 6-12 metres; human activities have impacted zone a great deal.			Width of riparian zone <6 metres; little or no riparian vegetation is present because of human activities.											
Left Bank	10	9	8	7	6	5	4	3	2	1	0										
Right Bank	10	9	8	7	6	5	4	3	2	1	0

	Brundiniella eumorpha						
	Clinotanypus sp.						
	Coelotanypus						
	Conchapelopia Group						
	Djalmabatista pulchra						
	Djalmabatista pulchra variant						
	Fittkauiyia serta						
	Guttipeloplia guttipennis						
	Labrundinia pilosella						
	Labrundinia sp.						
	Larsia sp.						
	Natarsia sp.						
	Natarsia sp. A						
	Nilotanypus fimbriatus						
	Nilotanypus sp.						
	Paramerina sp.						
	Pentaneura inconspicua						
	Pentaneura sp.						
	Procladius bellus						
	Procladius sp.						
	Tanypus carinatus						
	Tanypus punctipennis						
	Tanypus neopunctipennis						
	Tanypus sp.						
	Thienemannimyia GR						
	Zavrelimyia sp.						
	Culicidae						
	Anopheles sp.						
	Dixidae						
	Dixa sp.						
	Dixella sp.						
	Empididae						
	Hemerodromia sp.						
	Psychodidae						
	Simuliidae						
	Prosimulium sp.						
	Simulium sp.						
	Tabanidae						
	Tabanus sp.						
	Tipulidae						
	Antocha sp.						
	Dicranota sp.						
	Hexatoma sp.						
	Pilaria sp.						
	Pseudolimnophila sp.						
	Tipula sp.						
	Heteroptera						
	Belostomatidae						
	Belostoma sp.						

Appendix 6. Macroinvertebrate Bench Sheet

2017							
Corixidae							
Trichocorixa sp.							
Gerridae							
Nepidae							
Ranatra sp.							
Notonectidae							
Notonecta sp.							
Vellidae							
Microvelia sp.							
Rhagovelia obesa							
Lepidoptera							
Pyralidae							
Megaloptera							
Corydalidae							
Chauliodes pectinicornis							
Corydalus cornutus							
Nigronia fasciatus							
Nigronia serricornis							
Nigronia sp.							
Sialidae							
Sialis sp.							
Neuroptera							
Sisyridae							
Odonata							
Aeshnidae							
Basiaeschna janata							
Boyeria sp.							
Boyeria vinosa							
Nasiaeschna pentacantha							
Calopterygidae							
Calopteryx maculata							
Calopteryx sp.							
Hetaerina americana							
Hetaerina sp.							
Hetaerina tittia							
Coenagrionidae							
Argia sp.							
Enallagma sp.							
Enallagma/Ischnura							
Ischnura sp.							
Cordulegasteridae							
Cordulegaster maculata							
Cordulegaster sp.							
Corduliidae							
Epitheca sp.							
Helocordulia sp.							
Neurocordulia molesta							
Neurocordulia sp.							
Somatochlora sp.							
Tetragoneuria sp.							
Corduliidae/Libellulidae							
Gomphidae							
Arigomphus sp.							
Dromogomphus sp.							
Gomphus sp.							

Appendix 6. Macroinvertebrate Bench Sheet

2017							
	Hagenius brevistylus						
	Lanthus vernalis						
	Ophiogomphus sp.						
	Progomphus sp.						
	Stylogomphus albistylus						
	Stylurus sp.						
	Libellulidae						
	Erythemis simplicicollis						
	Libellula sp.						
	Pachydiplax longipennis						
	Macromiidae						
	Didymops transversa						
	Macromia sp.						
Mollusca							
	Gastropoda						
	Basommatophora						
	Ancylidae						
	Ferrissia sp.						
	Laevapex fuscus						
	Lymnaeidae						
	Pseudosuccinea columella						
	Physidae						
	Physella sp.						
	Planorbidae						
	Helisoma anceps						
	Helisoma trivolvis						
	Menetus dilitatus						
	Mesogastropoda						
	Hydrobiidae						
	Amnicola limosa						
	Somatogyrus virginicus						
	Pleuroceridae						
	Pleurocera (Elimia) catenaria.						
	Pleurocera (Elimia) proxima						
	Pleurocera (Elimia) sp.						
	Viviparidae						
	Campeloma sp.						
Pelecypoda							
	Heterodonta						
	Corbiculidae						
	Corbicula fluminea						
	Sphaeriidae						
	Eupera cubensis						
	Musculium sp.						
	Pisidium sp.						
	Sphaerium sp.						
Unionoida							
	Unionidae						
	Elliptio angustata						
	Elliptio complanata						
	Elliptio complanata/icterina						
	Elliptio icterina						
	Elliptio sp.						
	Villosa delumbis
